

Cloud Computing Patterns

<http://www.cloudcomputingpatterns.org>

Native Cloud Applications

- Two-Tier Cloud Application (290)**
Presentation and business logic is bundled to one stateless tier that is easy to scale. It is separated from the data tier that is harder to scale.
- Three-Tier Cloud Application (294)**
Presentation, business logic, and data handling are realized in separate tiers to scale them according to their individual requirements.
- Content Distribution Network (300)**
Applications component instances and data handled by them are globally distributed to meet access performance requirements.

Hybrid Cloud Applications

- Hybrid User Interface (304)**
Varying workload from a user group interacting asynchronously with an application is handled in an elastic environment.
- Hybrid Processing (308)**
Processing functionality is hosted in an elastic cloud while the remainder of an application resides in a static environment.
- Hybrid Data (311)**
Data of varying size is hosted in an elastic cloud while the remainder of an application resides in a static environment.
- Hybrid Backup (314)**
Data is periodically extracted from an application to be archived in an elastic cloud for disaster recovery purposes.
- Hybrid Backend (317)**
Backend functionality (data-intensive processing and storage) is experiencing varying workloads and is hosted in an elastic cloud.
- Hybrid Application Functions (320)**
Some application functionality provided by user interfaces, processing, and data handling is hosted in an elastic cloud.
- Hybrid Multimedia Web Application (323)**
Website content is mainly served from a static environment. Multimedia files are served from an elastic high-performance environment.
- Hybrid Development Environment (326)**
A production runtime environment is replicated and mocked in an elastic environment where applications are developed and tested.

Application Workloads

- Static Workload (26)**
IT resources with an equal utilization over time experience static workload.
- Periodic Workload (29)**
IT resources with a peaking utilization at reoccurring time intervals experience periodic workload.
- Once-in-a-lifetime Workload (33)**
IT resources with an equal utilization over time disturbed by a strong peak occurring only once experience once-in-a-lifetime workload.
- Unpredictable Workload (36)**
IT resources with a random and unforeseeable utilization over time experience unpredictable workload.
- Continuously Changing Workload (40)**
IT resources with a utilization that grows or shrinks constantly over time experience continuously changing workload.

Cloud Service Models & Cloud Deployment Types

- Infrastructure as a Service (IaaS) (45)**
Physical and virtual hardware IT resources are shared between customers to enable self-service, rapid elasticity, and pay-per-use pricing.
- Platform as a Service (PaaS) (49)**
An application hosting environment is shared between customers to enable self-service, rapid elasticity, and pay-per-use pricing.
- Software as a Service (SaaS) (55)**
Human-usable application software is shared between customers to enable self-service, rapid elasticity, and pay-per-use pricing.
- Public Cloud (62)**
IT resources are provided as a service to a very large customer group in order to enable elastic use of a static resource pool.
- Private Cloud (66)**
IT resources are provided as a service exclusively to one customer in order to meet requirements on privacy, security, and trust.
- Community Cloud (71)**
IT resources are provided as a service to multiple customers trusting each other in order to enable collaborative elastic use of resources.
- Hybrid Cloud (75)**
Different clouds and static data centers are integrated to form a homogeneous hosting environment.

Fundamental Architecture Styles

- Loose Coupling (156)**
A broker encapsulates concerns of communication partner location, implementation platform, time of communication, and data format.
- Distributed Application (160)**
A cloud application divides provided functionality among multiple application components that can be scaled out independently.

Application Components

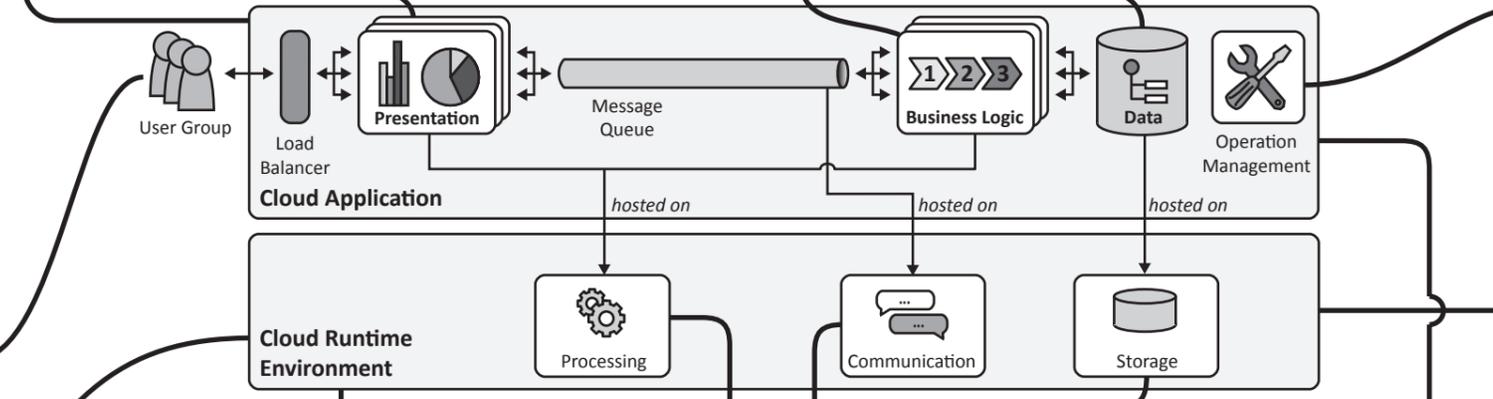

- Stateful Component (168)**
Multiple instances of a scaled-out application component synchronize their internal state to provide a unified behavior.
- Stateless Component (171)**
State is handled external of application components to ease scaling-out and to make the application more tolerant to component failures.
- Multi-Component Image (206)**
Virtual servers host multiple components that may not be active at all times to reduce provisioning and decommissioning operations.
- User Interface Component (175)**
Customizable user interfaces are accessed by humans. Application-internal interaction is realized asynchronously to ensure loose coupling.

Application Components

- Processing Component (180)**
Processing functionality is handled by elastically-scaled components. Functionality is made configurable to support different requirements.
- Batch Processing Component (185)**
Requests are delayed until environmental conditions make their processing feasible.
- Timeout-based Message Processor (204)**
Clients acknowledge message processing to ensure that messages are processed. If a message is not acknowledged it is processed again.
- Transaction-based Processor (201)**
Components receive messages or read data and process the obtained information under a transactional context to ensure processing.
- Idempotent Processor (197)**
Application functions detect duplicate messages and inconsistent data or are designed to be immune to these conditions.
- Data Access Component (188)**
Access to data is handled by components that isolate complexity, enable additional consistency, and ensure adjustability of data elements.
- Data Abstractor (194)**
Data is altered to inherently support eventually consistent data storage through the use of abstractions and approximations.

Application Management

- Provider Adapter (243)**
Provider interfaces are encapsulated to separate concerns of interactions with the provider from application functionality.
- Managed Configuration (247)**
Application components use a centrally stored configuration to provide a unified behavior that can be adjusted simultaneously.
- Elasticity Manager (250)**
The utilization of IT resources on which an application is hosted is used to adjust the number of required application component instances.
- Elastic Load Balancer (254)**
The number of synchronous accesses is used to adjust the number of required application component instances.
- Elastic Queue (257)**
The number of accesses via messaging is used to adjust the number of required application component instances.
- Watchdog (260)**
Applications cope with failures automatically by monitoring and replacing faulty application component instances.
- Elasticity Management Process (267)**
Application component instances are added and removed automatically to cope with increasing or decreasing workload.
- Feature Flag Management Process (271)**
If the cloud cannot provide required resources in time, some application features are degraded in order to keep vital features operational.
- Update Transition Process (275)**
When a new application component version becomes available, running application components are updated seamlessly.
- Standby Pooling Process (279)**
Application component instances are kept on standby to increase provisioning speed and utilize billing time-slots efficiently.
- Resiliency Management Process (283)**
Application components are checked for failures and replaced automatically without human intervention.

Cloud Environments

- Elastic Infrastructure (87)**
Hosting of virtual servers, disk storage, and configuration of network connectivity is offered via a self-service interface over a network.
- Elastic Platform (91)**
Middleware for the execution of applications, their communication, and data storage is offered via a self-service interface over a network.
- Node-based Availability (95)**
A cloud provider guarantees the availability of individual nodes, such as virtual servers, middleware, or hosted application components.
- Environment-based Availability (98)**
A cloud provider guarantees the availability of the environment hosting individual nodes, such as virtual servers or application components.

Processing Offerings

- Hypervisor (101)**
To enable the elasticity of clouds, the time required to provision and decommission servers is reduced through hardware virtualization.
- Execution Environment (104)**
To avoid duplicate implementation of functionality, applications are deployed to a hosting environment providing common functionality.
- Map Reduce (106)**
Large data sets to be processed are divided into smaller data chunks and distributed among processing application components.

Application Components

- Shared Component (210)**
A component is accessed by multiple tenants to leverage economies of scale.
- Tenant-isolated Component (214)**
A component avoids influences between tenants regarding assured performance, available storage capacity, and accessibility.

Storage Offerings

- Block Storage (110)**
Centralized storage is integrated into servers as a local hard drive to enable access to this storage via the local file system.
- Blob Storage (112)**
Data is provided in form of large files that are made available in a file system-like fashion.
- Relational Database (115)**
Data is structured according to a schema that is enforced during data manipulation and enables expressive queries of handled data.

Communication Offerings

- Virtual Networking (132)**
Networking resources are virtualized to enable customers to configure networks, firewalls, and remote access using a self-service interface.
- Message-oriented Middleware (136)**
Asynchronous communication is made robust and flexible by hiding the complexity of addressing, routing, or data formats.
- Exactly-once Delivery (141)**
The messaging system ensures that each message is delivered exactly once by filtering possible message duplicates automatically.

Cloud Integration

- Restricted Data Access Component (222)**
Data provided to clients from different environments is adjusted based on access restrictions.
- Message Mover (225)**
Messages are moved automatically between different cloud providers to provide unified access to application components using messaging.
- Application Component Proxy (228)**
An application component is made available in an environment from where it cannot be accessed directly by deploying a proxy.
- Compliant Data Replication (231)**
Data is replicated among multiple environments. Data is automatically obfuscated and deleted to meet laws and security regulations.
- Integration Provider (234)**
Integration functionality such as messaging and shared data is hosted by a separate provider to enable integration of hosting environments.

Multi-Tenancy

- Dedicated Component (218)**
Components providing critical functionality are provided exclusively to tenants while still allowing other components to be shared.

Storage Offerings

- Key-Value Storage (107)**
Semi-structured or unstructured data is stored with limited querying support but high-performance, availability, and flexibility.
- Strict Consistency (123)**
Data is stored at different locations to improve response time and failure resiliency while consistency of replicas is ensured at all times.
- Eventual Consistency (126)**
Performance and availability of data are increased by ensuring data consistency eventually and not at all times.

Communication Offerings

- At-least-once Delivery (144)**
In case of failures that lead to message loss, messages are retransmitted to assure they are delivered at least once.
- Transaction-based Delivery (146)**
Clients retrieve messages under a transactional context to ensure that messages are received by a handling component.
- Timeout-based Delivery (149)**
Clients acknowledge message receptions to ensure that messages are received properly.
